

An Introduction to Proof via Inquiry-Based Learning

Instructor Guide

Dana C. Ernst

August 16, 2022

This Instructor Guide is a work in progress! If you have questions about something not addressed in this guide, you can either submit an issue on [GitHub](#) or send me an email at dana.ernst@nau.edu. I want instructors that utilize *An Introduction to Proof via Inquiry-Based Learning* to be as successful as possible, so please reach out with questions or concerns.

Overview

An Introduction to Proof via Inquiry-Based Learning is intended to be used for a one-semester or quarter introduction to proof course (sometimes referred to as a transition to proof course). The purpose of the book is to introduce the reader to the process of constructing and writing formal and rigorous mathematical proofs. The intended audience is mathematics majors and minors. However, the book is also appropriate for anyone curious about mathematics and writing proofs. Most users of the book will have taken at least one semester of calculus, although other than some familiarity with a few standard functions in Chapter 8: Functions, content knowledge of calculus is not required.

In order to promote a more active participation in student learning, *An Introduction to Proof via Inquiry-Based Learning* adheres to an educational philosophy called inquiry-based learning (IBL). IBL is a student-centered method of teaching that engages students in sense-making activities and challenges them to create or discover mathematics. The book expects readers to actively engage with the topics at hand and to construct their own understanding. The reader will be given tasks requiring them to solve problems, conjecture, experiment, explore, create, and communicate. Rather than showing facts or a clear, smooth path to a solution, the book guides and mentors the reader through an adventure in mathematical discovery.

However, the book makes no assumptions about the specifics of how the instructor will choose to implement an IBL approach. Ultimately, the instructor should do what is best for their students. Generally speaking, students are told which problems and theorems to grapple with for the next class sessions, and then the majority of class time is devoted to students working in groups on unresolved solutions/proofs or having students present their proposed solutions/proofs to the rest of the class. Students should—as much as possible—be responsible for guiding the acquisition of knowledge and validating the ideas presented. That is, you should not be looking to the instructor as the sole authority. In an IBL course, instructor and students have joint responsibility for the depth and progress of the course. While effective IBL courses come in a variety of forms, they all possess a few essential ingredients. According to [Laursen and Rasmussen \(2019\)](#), the Four Pillars of IBL are:

- Students engage deeply with coherent and meaningful mathematical tasks.
- Students collaboratively process mathematical ideas.
- Instructors inquire into student thinking.
- Instructors foster equity in their design and facilitation choices.

The book can only address the first pillar while it is the responsibility of the instructor and class to develop a culture that provides an adequate environment for the remaining pillars to take root. Again, I would like to emphasize that the book is mostly agnostic about the approach that an instructor would take when teaching out of the book. Heck, I don't see any reason why an instructor couldn't use the book for a lecture-based class. Although that's certainly not what I had in mind when writing the book.

The book includes more content than one can expect to cover in a single semester or quarter. This allows the instructor/reader to pick and choose the sections that suit their needs and desires. Each chapter takes a focused approach to the included topics, but also includes many gentle exercises aimed at developing intuition.

The following sections form the core of the book and are likely the sections that an instructor would focus on in a one-semester introduction to proof course.

- Chapter 2: Mathematics and Logic. All sections.
- Chapter 3: Set Theory. Sections 3.1, 3.3, 3.4, and 3.5.
- Chapter 4: Induction. All sections.
- Chapter 7: Relations and Partitions. Sections 7.1, 7.2, and 7.3.
- Chapter 8: Functions. Sections 8.1, 8.2, 8.3, and 8.4.
- Chapter 9: Cardinality. All sections.

Time permitting, instructors can pick and choose topics from the remaining sections. I typically cover the core sections listed above together with Chapter 6: Three Famous Theorems during a single semester.

There are many useful resources available that instructors can utilize for designing an effective IBL/active learning experience for their students. The [Academy of Inquiry Based Learning](#) is a good place to get started. I also suggest consulting the MAA's [Instructional Practices Guide](#), which is a guide to evidence-based instructional practices in undergraduate mathematics. One effective approach to getting started with IBL is mimicking another instructor's approach and then refining for your purposes over time. Feel free to borrow as many ideas as you would like from how I set up the course I teach using *An Introduction to Proof via Inquiry-Based Learning*. You can find the syllabus, homework assignments, etc from two recent iterations of my course at the following links:

- [Fall 2021](#)
- [Spring 2020](#)

My Fall 2021 course utilized a version of the book that is nearly identical to the current version, but I happened to cover far less material than usual. I covered more ground in Spring 2020, but the version of the book I used that semester may look a bit different than the current version. I would consider the amount of material I covered in Spring 2020 to be fairly typical. The differences in the amount of material that I covered had nothing to do with the version of the book! Feel free to reach out with questions about how to set up your course or how to best make use of the book.

Evidence in Favor of Active Learning

If you are already using or considering using *An Introduction to Proof via Inquiry-Based Learning*, you likely don't need to be convinced of the merits of active learning. Nonetheless, below is very brief summary of some the data that supports the use of active learning.

Evidence in favor of some form of active engagement of students is strong across STEM disciplines. [Freeman et al. \(2014\)](#) conducted a meta-analysis of 225 studies of various forms of active learning, and found that students were 1.5 times more likely to fail in traditional courses as compared to active learning courses, and students in active learning courses outperformed students in traditional courses by 0.47 standard deviations on examinations and concept inventories. The following snippet from Freeman et al. (2014) captures the importance of utilizing active learning across STEM education:

“The results raise questions about the continued use of traditional lecturing as a control in research studies, and support active learning as the preferred, empirically validated teaching practice in regular classrooms.”

For IBL specifically, a research group from the University of Colorado Boulder led by Sandra Laursen conducted a comprehensive study of student outcomes in IBL undergraduate mathematics courses while linking these outcomes to students' and instructors' experiences of IBL (see [Laursen et al. 2011](#); [Laursen 2013](#); [Kogan and Laursen 2014](#); [Laursen et al. 2014](#)). This quasi-experimental, longitudinal study examined over 100 courses at four different campuses over a period that spanned two years.

On average over 60% of IBL class time was spent on student-centered activities including student-led presentations, discussion, and small-group work. In contrast, in non-IBL courses, 87% of class time was devoted to students' listening to an instructor talk. In addition, the IBL sections were rated more highly for a supportive classroom environment and students conveyed that engaging in meaningful mathematical tasks while collaborating was essential to their learning. Below is a brief summary of some of the outcomes of Laursen et al.'s work.

- After an IBL or comparative course, IBL students reported higher learning gains than their non-IBL peers, across cognitive, affective, and collaborative domains of learning.
- In later courses, students who had taken an IBL course earned grades as good or better than those of students who took non-IBL sections, despite having “covered” less material.
- Non-IBL courses show a marked gender gap: across the board, women reported lower learning gains and less supportive attitudes than did men (effect size 0.4–0.5). Women's confidence and sense of mastery of mathematics, and their interest in continued study of math were lower. This difference appears to be primarily affective, not due to real differences in women's mathematical preparation or achievement.

- This gender gap was erased in IBL classes: women’s learning gains were equal to men’s, and their confidence and intent to persist similar. IBL approaches leveled the playing field for women, fixing a course that is problematic for women yet with no harm to men.

You can watch a short YouTube video of Sandra Laursen summarizing most of the recent research about inquiry-based learning [here](#). The [Conference Board of the Mathematical Sciences \(CBMS\)](#) wrote the following in their [position statement on active learning in 2016](#):

“... we call on institutions of higher education, mathematics departments and the mathematics faculty, public policy-makers, and funding agencies to invest time and resources to ensure that effective active learning is incorporated into post-secondary mathematics classrooms.”

In addition, the Manifesto of the [MAA Instructional Practices Guide](#) states:

“We must gather the courage to advocate beyond our own classroom for student-centered instructional strategies that promote equitable access to mathematics for all students. We stand at a crossroads, and we must choose the path of transformation in order to fulfill our professional responsibility to our students.”

Structure of the Textbook

As students read the book, they should be digesting the material in a meaningful way. In addition to reading and understanding new definitions and their related concepts, students will be asked to complete problems aimed at solidifying their understanding of the material. In particular, the reader is asked to make conjectures, produce counterexamples, and prove theorems. All of these tasks will almost always be challenging.

The items labeled as **Definition** and **Example** are meant to be read and digested. However, the items labeled as **Problem**, **Theorem**, and **Corollary** require action on the reader’s part. Items labeled as **Problem** are sort of a mixed bag. Some Problems are computational in nature and aimed at improving understanding of a particular concept while others ask the reader to provide a counterexample for a statement if it is false or to provide a proof if the statement is true. Items with the **Theorem** and **Corollary** designation are mathematical facts and the intention is for the reader to produce a valid proof of the given statement. All of this is spelled out in the Introduction of the book, but I suggest taking the time to communicate this to your students.

Oftentimes, the problems and theorems are guiding the reader towards a substantial, more general result. Other times, they are designed to get the reader to apply ideas in a new way. Please take the time to tell your students that every task in the book is doable but sometimes very challenging. They may not be successful on their first, or even second or third try. This is okay! Remind them of this often.

Discussion of new topics is typically kept at a minimum and there are very few examples in the book. This is intentional. One of the objectives of the items labeled as **Problem** is for the reader to produce the examples needed to internalize unfamiliar concepts. The overarching goal of the book is to help the reader develop a deep and meaningful understanding of the processes of producing mathematics by putting them in direct contact with mathematical phenomena.

General Comments

blah

Chapter 1: Introduction

I ask my students to read this short chapter and then take the time in class to highlight the content in **Section 1.4**. Despite this, I always have at least one student that asks me what they are supposed to do the first time I assign a theorem. At a minimum, I would ask students to read **Sections 1.2–1.4**.

Chapter 2: Mathematics and Logic

Most instructors will likely choose to cover Chapter 2 as part of their course. While this chapter sets the stage for what is to come later in the book, I caution instructors from getting too bogged down here. I recommend covering this chapter as swiftly as your students can manage, so that you have time later for more challenging topics. In my opinion, you can crank through this chapter without causing any damage. If necessary, you can always return to the foundation in this chapter as needed. None of the mathematical theorems (in contrast to the logical theorems, e.g., **Theorem 2.26**) are needed in future chapters. The sole purpose of the mathematical theorems in Chapter 2 is to provide an onramp to proving theorems in a familiar context.

Section 2.1 is a bit unusual as it asks students to jump right into proving theorems without any initial guidance. This is intentional, and in my experience is a very effective way to start the course. First, it gives you a sense of where your students are at in terms of their general understanding, or lack thereof, mathematical proofs. I think you will be surprised at what students are capable of without being explicitly told how to write a proof. Second, and more importantly, this section develops an intellectual need for more rigor and more structure. Take the time to communicate to your students what the purpose of this section is. Emphasize to them that they should just jump in and try their hand at writing proofs without too much concern for whether they are “doing it the right way.” Lots of interesting issues will bubble to the surface and you will have to pick and choose which topics you want to carefully address now versus later in the semester. **Theorem 2.2** is the first theorem in the book and you should remind students that the intended task for theorems is to prove them.

The definitions for even and odd integers are given in **Definition 2.1**, but many students will attempt to use their favorite characterizations that they are familiar with. For example, they might say that an integer is even if it is divisible by 2. While this is certainly true, they won’t encounter the definition of “divides” until **Definition 2.5**. It’s a good idea to point out that this characterization of even follows immediately from **Definitions 2.1** and **2.5**. Students are also often surprised that negative integers can be odd or even.

You will have to decide how firm of a stance you want to take on phrases like “even integer” versus “even number.” While the former is certainly the correct choice of language, my view is that the adjectives “even” and “odd” only refer to integers, so there shouldn’t be much confusion when one says, “even number.” You should decide in advance how you want to approach this issue. At the very least, be sure to have a conversation about this with your students.

To save some time, notice that I wrote, “For the remainder of this section, you may assume that every integer is either even or odd but never both” in the paragraph below **Definition 2.1**. This is something you should point out to students and be sure to tell them that officially this is something one would need to prove. We will be more careful in later chapters.

Problem 2.6 and the paragraph that follows address the difference between “ n divides m ” versus “ m divided by n .” The former is a sentence while the latter is a noun (i.e., the number one obtains after dividing m by n). You should be prepared for this confusion to rear its head multiple times during your course.

Corollary 2.9 is the first encounter with a corollary in the book. It’s a good idea to remind students what a corollary is (even though there is a reminder in the text right above **Corollary 2.9**). One can prove **Corollary 2.9** by appealing to **Theorem 2.8** or directly. I always find a way to make sure both approaches get presented (by either students or by me) and then we take a moment to discuss the fact that we can appeal to previous results or return to the definition and prove things from scratch.

The same two approaches could be employed in the proof of **Theorem 2.10**. In fact, perhaps I should have called Theorem 2.10 a corollary.

Definition 2.18(d) introduces the definition of the truth value of a conditional statement. It’s important to emphasize to students that this is a definition. Students are often disturbed by the fact that $A \implies B$ is true when A is false no matter what the truth value of B is. The purpose of **Problem 2.23** is to help students reconcile any cognitive dissonance that students might have with this definition.

While **Section 2.1** asks students to jump in head first without a formal understanding of what it was we were doing, **Section 2.2** hits the reset button and takes a more careful approach while introducing the basics of propositional logic. One detail you could get lots in the weeds on is whether a given English-language sentence is a proposition or not. My suggestion is to not lose focus here. There are lots of subtle issues that I have chosen not to formally address in the book.

My suggestion is minimize the importance of the symbolic logic (e.g., strings utilizing symbols such as \forall , \exists , \wedge , \vee , \implies , etc.) presented in **Sections 2.2–2.5**. I think it is important for students to be exposed to symbolic logic, but I essentially abandon it after **Section 2.5**. Discourage your students from using the formal symbolism in their mathematical proofs.

The intended proof technique for most of the theorems in **Section 2.2** is create a truth table. You’ll likely need to provide some guidance to your students about how many intermediate columns they should include in their truth tables. **Corollary 2.41** can be proved by either creating a truth table or by appealing to **Theorem 2.40**, **Problem 2.27**, and **Theorem 2.25** and then relying on the transitivity of logical equivalence. Note that I do not explicitly state transitivity of logical equivalence anywhere in the textbook.

While you could skip **Theorem 2.56** and **Theorem 2.57**, these theorems provide a first opportunity to practice writing a proof by contradiction and a biconditional proof, respectively.

One thing worth pointing out is that there is an implicit universal quantifier in front of all statements of the form “if $A(x)$, then $B(x)$ ”, where $A(x)$ and $B(x)$ are predicates and x is some variable. I attempt to address this issue just after **Problem 2.67**. This is standard convention in mathematics and is definitely worth pointing out to your students. The statement “For all x , if $A(x)$, then $B(x)$ ” is a proposition. This statement may sometimes be written in two sentences, where the first sentence

bounds the variable. For example, “Let n be a natural number. If $A(n)$, then $B(n)$.” Another way to write the same statement would be “If n is a natural number such that $A(n)$, then $B(n)$.” This is how most of the theorems in Sections 2.1 and 2.3 are written. More commonly, if the universe of discourse is understood (or can be inferred), one might simply write “If $A(n)$, then $B(n)$.” Officially, “If $A(n)$, then $B(n)$ ” is a predicate, but if we take this as short hand for “For all n , if $A(n)$, then $B(n)$ ”, we have a proposition.

It’s not crucial that you cover **Problems 2.70-2.73**, but I do find it helpful for students to practice the conversion from plain English to symbolic logic and vice versa. The idea in **Problem 2.73** is probably a good one to discuss.

Students struggle with proving **Theorem 2.76**, which handles the negation of quantifiers. This is a good example where you must think very deeply, but there isn’t much to write down. This is a good example of a theorem where I would probably ask students to prove one of the two parts (leaving it to them to choose which part).

Problem 2.86 is time consuming. One way you could speed things up is to tell them which parts are true versus false. You could also skip some of the parts. While **Theorems 2.89** and **2.90** are not crucial for later, they could be skipped, but I recommend doing at least one of them. **Theorem 2.91** is also not crucial for future chapters, but provides an opportunity for proving uniqueness. It’s a long while before this issue crops up again (the next instance is **Theorem 4.36**), so you could defer the discussion about uniqueness until it is absolutely necessary.

One detail that gets swept under the rug in **Sections 2.4** and **2.5** is that we discuss the truth value of conditional propositions in **Definition 2.18** and then take for granted that we can apply the same structure to conditional statements involving predicates. For better or worse, this seems to be the standard approach in introduction to proof books. My personal take is that I don’t want to get bogged down in these sorts of pedantic details, but if you feel otherwise, you should address the issue carefully for your students.

Chapter 3: Set Theory

Unless you know your students are familiar with the content in Chapter 3, I think covering this chapter is essential. In my experience, once students get the hang of “element chasing”, this chapter goes smoothly. You could skip **Section 3.2** about paradoxes or simply assign it as outside reading. However, in my experience, students tend to be captivated by paradoxes. Moreover, at least at my institution, there isn’t another place in the curriculum that a student would be exposed to the idea of a paradox in mathematics. If you have intentions of ever discussing the Axiom of Choice (**Axiom 3.43**), you should consider discussing **Section 3.2**.

Taking the time to carefully outline a skeleton proof for proving $A \subseteq B$ in **Problem 3.9** will help tremendously as you progress through Chapter 3.

Theorem 3.20 provides an excellent opportunity to showcase two different proof techniques. One method is to prove the two set containments by “element chasing”. The second method involves a chain of equality of sets. I recommend showcasing both approaches. For example, here is a one sentence proof of **Theorem 3.20**.

Proof of Theorem 3.20. Let A and B be sets in some universe of discourse U . We see that

$$\begin{aligned} A \setminus B &= \{x \in U \mid x \in A \text{ and } x \notin B\} \\ &= \{x \in U \mid x \in A \text{ and } x \in B^c\} \\ &= \{x \in U \mid x \in A \cap B^c\} \\ &= A \cap B^c. \end{aligned}$$

□

For **Theorems 3.21** and **3.22**, I typically ask students to prove one of Parts (a) or (b).

Problem 3.23 is not necessary for later, but I find it to be a good exercise for students.

Problem 3.31 is time consuming, but extremely worthwhile. One shortcut you could take is telling the students which parts are true versus false.

In my experience, **Section 3.3** is probably the most challenging section in Chapter 3. For this reason, I wouldn't skip any of the easy exercises (e.g., **Problems 3.33–3.3.37**).

For **Theorems 3.41** and **3.42**, I typically ask students to prove one of Parts (a) or (b). For both theorems, I encourage students to prove both set containments as opposed to attempting to chain together equality of sets.

If you have planes to cover **Chapters 7** or **8**, you will need to cover at least parts of **Section 3.5**. One can safely skip **Theorem 3.56–Problem 3.62**, but I enjoy covering this material if time allows. **Problem 3.61** is time consuming and provides a nice challenge for students. **Problem 3.62** is also a fun challenge, but certainly isn't necessary.

Chapter 4: Induction

Most instructors will likely cover Chapter 4. If your students already have some familiarity with induction, you can probably find places to cut corners. However, in my experience, I find it best to assume students know nothing about induction and give it a careful treatment.

After students tackle **Theorem 4.2** (Principle of Mathematical Induction), I spend time discussing **Skeleton Proof 4.3** and then often present the first few induction proofs in order to set the standard for what the proofs should look like. One potentially misleading aspect of **Skeleton Proof 4.3**, is that students might think that are supposed to actually write “ $P(k)$ ” and “ $P(k+1)$ ” in their proofs. I discourage this. Instead, I instruct students to write down whatever the actual predicate is for $P(k)$. For example, for the inductive step of the proof of **Theorem 4.4**, I would want students to write, “Let $k \in \mathbb{N}$ and assume $\sum_{i=1}^k i = \frac{k(k+1)}{2}$ is true.” In fact, I think we can safely omit the phrase “is true” and simply write, “Let $k \in \mathbb{N}$ and assume $\sum_{i=1}^k i = \frac{k(k+1)}{2}$.” If I present a few induction proofs, we can iron out these details quickly.

Theorem 4.7 and **Problem 4.8** provide an opportunity for students to wrestle with induction proofs that are simply manipulation of strings of symbols. I highly recommend not skipping these two. **Problem 4.8** provided inspiration for the cover of the print version of the book.

While I make sure we witness a precise proof of **Theorem 4.2**, sometimes I might wave my hands a bit and skimp on a rigorous proof of **Theorem 4.9**, which states that we do not need to start induction at $k = 1$. The proof of **Theorem 4.9** is simply a clever adjustment to the proof of **Theorem 4.2**.

I view **Theorem 4.11** as essential, but you definitely do not need to assign all of **Theorem 4.12–4.23** as none of these are needed for later. I typically ask students to proof any two of **Theorem 4.12–4.23**. **Problem 4.24** is not essential but provides an excellent opportunity for students to tinker and practice the skills they have developed.

The proof of **Theorem 4.25** (Principle of Complete Mathematical Induction) often causes some confusion for students. This provides a good opportunity to discuss the notion of “weaker” versus “stronger” hypotheses. We know that The Principle of Mathematical Induction is true and this theorem has weaker hypotheses than its complete analogue, and hence the Principle of Complete Mathematical Induction must also be true. Emphasize to students that despite the name, complete induction is not any stronger or more powerful than ordinary induction. One can prove that the two notions are equivalent, but I’ve chosen not to formally ask students to prove this fact.

I suggest you pick and choose a few of **Theorem 4.27–Problem 4.34** to have students to work on. Note that **Problem 4.34** involves the Fibonacci numbers, which are introduced in **Problem 4.29**.

The goal of **Section 4.5** is to prove **Theorem 4.38** (Well-Ordering Principle) and two generalizations that appear in **Theorems 4.39** and **4.40**. My intended proof of the Well-Ordering Principle is to utilize **Theorem 4.25** (Principle of Complete Mathematical Induction). This is a nice application of induction. If you plan to cover **Sections 5.1** or **6.1**, you will need the Well-Ordering Principle. Specifically, the Well-Ordering Principle is needed in the proofs of **Theorems 6.6**, **6.7**, and **6.13**, and its generalization **Theorem 4.40** is needed in the proof of **Theorem 5.46**. Note that I have included the proof of **Theorem 6.7** (Division Algorithm) in Chapter 6.

Chapter 5: The Real Numbers

Chapter 6: Three Famous Theorems

Chapter 7: Relations and Partitions

Chapter 8: Functions

Chapter 9: Cardinality
