Chapter 3

Permutations

For $n \in \mathbb{N}$, we define $\boxed{[n] : \{1, 2, \ldots, n\}}$. That is, $[n]$ is just clever shorthand for the set containing 1 through n. This notation is meant to resemble interval notation.

For $k \in \mathbb{N}$ and a nonempty set A, a **k-permutation** of A is an injective function $w : [k] \to A$. The set of all k-permutations of A is denoted by $\boxed{S_{A,k}}$. If A happens to be the set $[n]$, we use the notation $\boxed{S_{n,k}}$. And if $n = k$, we write $\boxed{S_n := S_{n,n}}$ and refer to each n-permutation in S_n as a **permutation**. Let $\boxed{P(n,k) := |S_{n,k}|}$. By convention, we set $\boxed{P(n,0) := 1}$, including the case when $n = 0$.

We can denote a k-permutation as a string $w = w(1)w(2)\cdots w(k)$, where each entry $w(i)$ that appears in the string is unique (since w is an injection). In other words, we can think of a k-permutation as a linearly ordered arrangement of k of n objects.

Problem 3.1. Complete the following.

(a) Write down all of the elements in S_3. What is $P(3,3)$?

(b) Write down all of the elements in $S_{4,3}$. What is $P(4,3)$?

Recall that for $n \in \mathbb{N}$, the **factorial** of n is defined $\boxed{n! := n \cdot (n-1) \cdots 2 \cdot 1}$, and we define $\boxed{0! := 1}$ for convenience.

Problem 3.2. Consider the collection of k-permutations in $S_{n,k}$ with $1 \leq k \leq n$. Explain why $P(n,k)$ is equal to the number of nonattacking rook arrangements on an $n \times k$ chess board. *Hint:* Establish a bijection between the collection of nonattacking rook arrangements on an $n \times k$ chess board and the collection of k-permutations.

Theorem 3.3. For $1 \leq k \leq n$, we have

$$\boxed{P(n,k) = n \cdot (n-1) \cdots (n+1-k) = \frac{n!}{(n-k)!}.}$$

Note that as a special case of the formula above, we have $|S_n| = P(n,n) = n!$ and we obtain

$$\boxed{P(0,0) = \frac{0!}{(0-0)!} = 1} \quad \text{and} \quad \boxed{P(n,0) = \frac{n!}{(n-0)!} = 1.}$$

Problem 3.4. How many strings of length three are there using letters from $\{a, b, c, d, e, f, g\}$ if the letters in the string are not repeated?

Problem 3.5. There are 8 finalists at the Olympic Games 100 meters sprint. Assume there are no ties.

(a) How many ways are there for the runners to finish?

(b) How many ways are there for the runners to get gold, silver, bronze?

(c) How many ways are there for the runners to get gold, silver, bronze given that Usain Bolt is sure to get the gold medal?

Problem 3.6. If $1 \leq k \leq n$, prove that $\boxed{P(n,k) = P(n-1,k) + kP(n-1,k-1)}$, both using the formula in Theorem 3.3, and separately using the definition of k-permutations together with the bijection principle.

The formula in the previous problem is an example of a recurrence relation, which will be a topic of focus in a later chapter.

Interpreting a permutation as a linearly ordered arrangement of object (i.e., string), a **circular permutation** is similar to a permutation except the objects are arranged on a circle, so that there is no beginning or end. We can present a circular permutation w of length n as in Figure 3.1. Each $w(i)$ is a distinct value from $[n]$ and the convention is to place $w(n)$ next to $w(1)$.

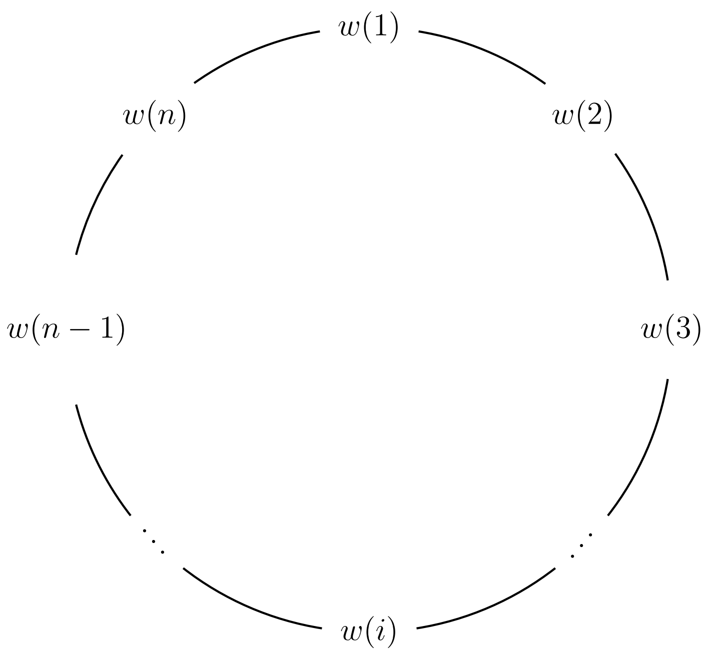

Figure 3.1: Representation of a circular permutation.

We encountered circular permutations back in Problem 1.39 when we counted circular seating arrangements of six friends sitting around a circle to play a game. Recall that the trick in that problem was to make use of the Division Principle.

Problem 3.7. How many circular permutations are there of length n?

More coming soon...
