

Enumerative Combinatorics

Dana C. Ernst

Northern Arizona University
Version Fall 2026

This book is intended to be a problem sequence for a one-semester graduate enumerative combinatorics course that utilizes an inquiry-based learning (IBL) approach. You may not modify the content of this book without expressed consent of the author.

Contents

1	Introduction	3

2	Combinatorial Structures	6

The mathematician does not study pure mathematics because it is useful; he studies it because he delights in it, and he delights in it because it is beautiful.

Henri Poincaré, mathematician & physicist

Chapter 1

Introduction

1.1 What is This Course All About?

This course focuses on [enumerative combinatorics](#) with an introduction to [generating function](#) techniques.

This course will use an [inquiry-based learning](#) (IBL) to learning combinatorics. Rather than spending most of class listening to lectures, you will spend substantial time exploring problems, developing arguments, presenting solutions, and discussing the mathematics with your classmates.

Outside of class, you may use whatever resources help you learn—including books, websites, classmates, and AI tools such as ChatGPT. The important distinction is between **finding a solution** and **understanding the mathematics**. When you come to class, you should be prepared to explain, defend, critique, and adapt the ideas you encountered.

Because outside resources are readily available, homework and preparation will be relatively low-stakes. Your understanding will be assessed primarily through your mathematical contributions in class and regular short, individual, no-resource assessments. In short:

Use whatever helps you learn. Be prepared to demonstrate that you learned it.

1.2 Inquiry-Based Learning

Mathematics is not about calculations, but ideas. My goal as a teacher is to provide students with the opportunity to grapple with these ideas and to be immersed in the process of mathematical discovery. Repeatedly engaging in this process hones the mind and develops mental maturity marked by clear and rigorous thinking. Like music and art, mathematics provides an opportunity for enrichment, experiencing beauty, elegance, and aesthetic value. The medium of a painter is color and shape, whereas the medium of a mathematician is abstract thought. The creative aspect of mathematics is what captivates me and fuels my motivation to keep learning and exploring.

While the content we teach our students is important, it is not enough. An education must prepare individuals to ask and explore questions in contexts that do not yet exist and to be able to tackle problems they have never encountered. It is important that we put these issues front and center and place an explicit focus on students producing, rather than consuming, knowledge. If we truly want our students to be independent, inquisitive, and persistent, then we need to provide them with the means to acquire these skills. Their viability as a professional in the modern workforce depends on their ability to embrace this mindset.

When I started teaching, I mimicked the experiences I had as a student. Because it was all I knew, I lectured. By standard metrics, this seemed to work out just fine. Glowing student and peer evaluations, as well as reoccurring teaching awards, indicated that I was effectively doing my job. People consistently told me that I was an excellent teacher. However, two observations made me reconsider how well I was really doing. Namely, many of my students seemed to depend on me to be successful, and second, they retained only some of what I had taught them. In the words of Dylan Retsek:

“Things my students claim that I taught them masterfully, they don’t know.”

Inspired by a desire to address these concerns, I began transitioning away from direct instruction towards a more student-centered approach. The goals and philosophy behind inquiry-based learning (IBL) resonate deeply with my ideals, which is why I have embraced this paradigm. According to the Academy of Inquiry-Based Learning, IBL is a method of teaching that engages students in sense-making activities. Students are given tasks requiring them to solve problems, conjecture, experiment, explore, create, and communicate—all those wonderful skills and habits of mind that mathematicians engage in regularly.

In an IBL course, instructor and students have joint responsibility for the depth and progress of the course. While effective IBL courses come in a variety of forms, they all possess a few essential ingredients. According to [Laursen and Rasmussen \(2019\)](#), the Four Pillars of IBL are:

- Students engage deeply with coherent and meaningful mathematical tasks.
- Students collaboratively process mathematical ideas.
- Instructors inquire into student thinking.
- Instructors foster equity in their design and facilitation choices.

This book can only address the first pillar while it is the responsibility of your instructor and class to develop a culture that provides an adequate environment for the remaining pillars to take root.

Just like learning to play an instrument or sport, you will have to learn new skills and ideas. Along this journey, you should expect a cycle of victory and defeat, experiencing a full range of emotions. Sometimes you will feel exhilarated, other times you might be seemingly paralyzed by extreme confusion. You will experience struggle and failure

before you experience understanding. This is part of the normal learning process. If you are doing things well, you should be confused on a regular basis. Productive struggle and mistakes provide opportunities for growth. As the author of this text, I am here to guide and challenge you, but I cannot do the learning for you, just as a music teacher cannot move your fingers and your heart for you.

You could view this book as mountaineering guidebook. I have provided a list of mountains to summit, sometimes indicating which trailhead to start at or which trail to follow. There will always be multiple routes to top, some more challenging than others. Some summits you will attain quickly and easily, others might require a multi-day expedition. Oftentimes, your journey will be laced with false summits. Some summits will be obscured by clouds. Sometimes you will have to wait out a storm, perhaps turning around and attempting another route, or even attempting to summit on a different day after the weather has cleared. The strength, fitness, and endurance you gain along the way will allow you to take on more and more challenging, and often beautiful, terrain. Do not forget to take in the view from the top! The joy you feel from overcoming obstacles and reaching each summit under your own will and power has the potential to be life changing. But make no mistake, the journey is vastly more important than the destinations.

Don't fear failure. Not failure, but low aim, is the crime. In great attempts it is glorious even to fail.

Chapter 2

Combinatorial Structures

One of our objectives is to study combinatorial structures that arise in mathematics, with an eye towards enumeration and classification. We will begin by investigating several sets of discrete mathematical objects and exploring the connections among them. In no particular order, here are some combinatorial species¹ we may encounter throughout the semester:

Binary String	Pixel Strip	Lattice Path
Starfolks Path	Compositions	Pebble Piles
Domino Stacking	Domino Tiling	Permutation
Nonattacking Rooks	Sparse Strip	Odd Composition
Binary Tree	Increasing Tree	Triangulated Polygon
Ballot Path	Noncrossing Partition	Parking Function
Unlabeled Tree	Set Partition	Integer Partition
Dodger Rooks	Cayley Permutation	Fubini Arrangement
Fraenkel Tree	Knuth Rooks	Penrose Doodle

Note that I invented some of the names mentioned above. Figure 2.1 provides a few examples of individuals one can find among the species mentioned above.

Figure 2.1: Examples of combinatorial species.

Below are some questions we should ponder when exploring a new species:

¹In this context, I am using the word “species” in a colloquial sense. Later in the semester, this word will have a more precise mathematical meaning.

- What patterns do we see?
- How do they “grow”?
- What is a sensible definition of the species? How does your definition tie in to the **index** n and the **rank** r ?
- Can you provide a generic example with index $n = 10$? For your example, what is r ?
- How many objects are there of index n ? Is there a nice formula?
- How many objects are there of index n and rank r ? Is there a nice formula?
- For a fixed index n how do you generate all the possibilities? What is the simplest/most efficient way to generate them?
- How does this species relate to other species we have studied?

You may not be able to answer some of these questions immediately, and that’s okay. The goals here are to have a variety of examples at our finger tips and to start a taxonomy of combinatorial species.

Problem 2.1. For each of the species you encountered in class, complete the following.

- List the name of the species.
- Provide a working definition for the species. Your definition should include mention of the index n and the rank r , including the domain for n (and possibly r). For example, your definition might start as, “A *dinglehopper* of index $n \in \mathbb{N} \cup \{0\}$ and rank r is...”
- Provide a generic example for index $n = 10$. For your example, specify the rank r . Your example should illustrate most or all of the key features and not be too “boring.”
- Provide a table of values that enumerates the number of structures of index n for small n . Your table should start at either $n = 0$ or $n = 1$ depending on the species and it should look something like the following:

n	0	1	2	3	4	5
count	1	1	2	3	5	8

- If you can, write down a formula (either a closed form or recursive) that counts the number of structures of index n . Justify your answer. Please do not look this up or ask AI. If you cannot do it at this time, I would prefer we leave it blank!
- Now, provide a table of values that enumerates the number of structures of index n and rank r for small values of n and r . Your table should start at either $n = 0$ or $n = 1$ and $r = 0$ or $r = 1$ depending on the species and it should resemble the following (where n labels the rows and r labels the columns):

$n \backslash r$	0	1	2	3	4	5
0	1					
1	1	1				
2	1	2	1			
3	1	3	3	1		
4	1	4	6	4	1	
5	1	5	10	10	5	1

- (g) Ignoring the row labels, what happens if you sum the enteries in a row of your table in part (f)?
- (h) If you can, write down a formula (either a closed form or recursive) that counts the number of structures of index n and rank r . Justify your answer. Please do not look this up or ask AI. If you cannot do it at this time, I would prefer we leave it blank!
- (i) Are there any other species you have already encountered that seems related to this species?
